

## Approved baseline methodology AM0028

### “Catalytic N<sub>2</sub>O destruction in the tail gas of Nitric Acid or Caprolactam Production Plants”

#### Sources

This baseline methodology is based on NM0111 “Baseline Methodology for catalytic N<sub>2</sub>O destruction in the tail gas of Nitric Acid Plants” submitted by Carbon Projektentwicklung GmbH.

For more information regarding the proposals and their consideration by the Executive Board please refer to <http://cdm.unfccc.int/methodologies/PAmethodologies/approved.html>.

This methodology also refers to the latest version of the “Tool for the demonstration and assessment of additionality”.

#### Applicability

The proposed methodology is applicable to project activities that destroy N<sub>2</sub>O emissions either by catalytic decomposition or catalytic reduction of N<sub>2</sub>O in the tail gas of nitric acid or caprolactam production<sup>1</sup> plants (i.e. tertiary destruction), where the following conditions apply:

- The applicability is limited to the existing production capacity measured in tonnes of nitric acid or caprolactam, where the commercial production had began no later than 31 December 2005. Definition of “existing” production capacity is applied for the process with the existing ammonia oxidization reactor where N<sub>2</sub>O is generated and not for the process with new ammonia oxidizer. Existing production “capacity” is defined as the designed capacity, measured in tons of nitric acid or caprolactam per year;
- Existing caprolactam plants are limited to those employing the Raschig process not using any external sources of nitrogen compounds other than feed ammonia;
- The project activity will not result in shut down of an existing N<sub>2</sub>O destruction or abatement facility at the nitric acid or caprolactam production plant;
- The project activity shall not affect the nitric acid or caprolactam production level;
- The project activity will not cause an increase in NO<sub>x</sub> emissions;
- In case a DeNO<sub>x</sub> unit is already installed prior to the start of the project activity, the installed DeNO<sub>x</sub> is a Selective Catalytic Reduction (SCR) DeNO<sub>x</sub> unit;
- The N<sub>2</sub>O concentration in the flow at the inlet and the outlet of the catalytic N<sub>2</sub>O destruction facility is measurable.

This baseline methodology shall be used in conjunction with revision of the approved monitoring methodology for AM0028 (Catalytic N<sub>2</sub>O destruction in the tail gas of Nitric Acid or Caprolactam Production Plants).

---

<sup>1</sup> Caprolactam Production Plants including the ammonia oxidation reactor (AOR) where N<sub>2</sub>O is generated.

## Project boundary

For the purpose of determining project activity emissions, project participants shall include the followings in the project boundary:

- N<sub>2</sub>O concentration in the flow stream of the tail gas;
- In case no SCR DeNOX unit has been installed prior to the start of the project activity, GHG emissions related to the production of ammonia used for the NO<sub>x</sub> reduction will be considered as project emissions. In case a SCR DeNOX unit has been installed prior to the start of the project activity, GHG emissions related to the production of ammonia used for NO<sub>x</sub> reduction will not be considered as project emissions;
- Hydrocarbons as a reducing agent to enhance the efficiency of a N<sub>2</sub>O catalytic reduction facility.

For the purpose of determining baseline emissions, project participants shall include the following emission sources:

- N<sub>2</sub>O concentration in the flow stream of the tail gas;
- In case no SCR DeNOX unit has been installed prior to the start of the project activity, GHG emissions related to the production of ammonia used for NO<sub>x</sub> reduction will be considered zero in the baseline. In case SCR DeNOX unit has been installed prior to the start of the project activity, GHG emissions related to the production of ammonia used for NO<sub>x</sub> reduction will not be considered.

Table 1 illustrates which emissions sources are included and which are excluded from the project boundary for determination of both baseline and project emissions.

**Table 1: Overview on emission sources included or excluded from the project boundary****Baseline Emissions**

<b>Source</b>	<b>Gas</b>		<b>Justification/Explanation</b>
Emissions of N <sub>2</sub> O as a result of side reaction to the nitric acid or caprolactam production process	N <sub>2</sub> O	Included	Main emission source, taking national N <sub>2</sub> O emission regulations into account
Emissions related to the production of ammonia used for NO <sub>x</sub> reduction  (Attention: Ammonia used for NO <sub>x</sub> -reduction does not cause GHG emissions, only the production of ammonia causes GHG emissions)	CO <sub>2</sub> CH <sub>4</sub> N <sub>2</sub> O	Included	In case SCR DeNOX unit is already installed prior to the project start: ammonia input for SCR is considered to be of the same magnitude to project related ammonia input for NO <sub>x</sub> reduction. Baseline emissions and project emissions are similar and therefore not considered for calculation.  In case no SCR DeNOX-unit is already installed prior to the project start: ammonia input for NO <sub>x</sub> reduction is considered 0 for baseline emissions
N <sub>2</sub> O emissions from SCR DeNOX-unit	N <sub>2</sub> O	Excluded	The presence of a SCR DeNOX unit tends to increase the N <sub>2</sub> O emissions. Therefore the <i>ex post</i> measurement of the baseline emissions at the inlet of the N <sub>2</sub> O destruction facility represents a conservative determination of the baseline N <sub>2</sub> O emissions.

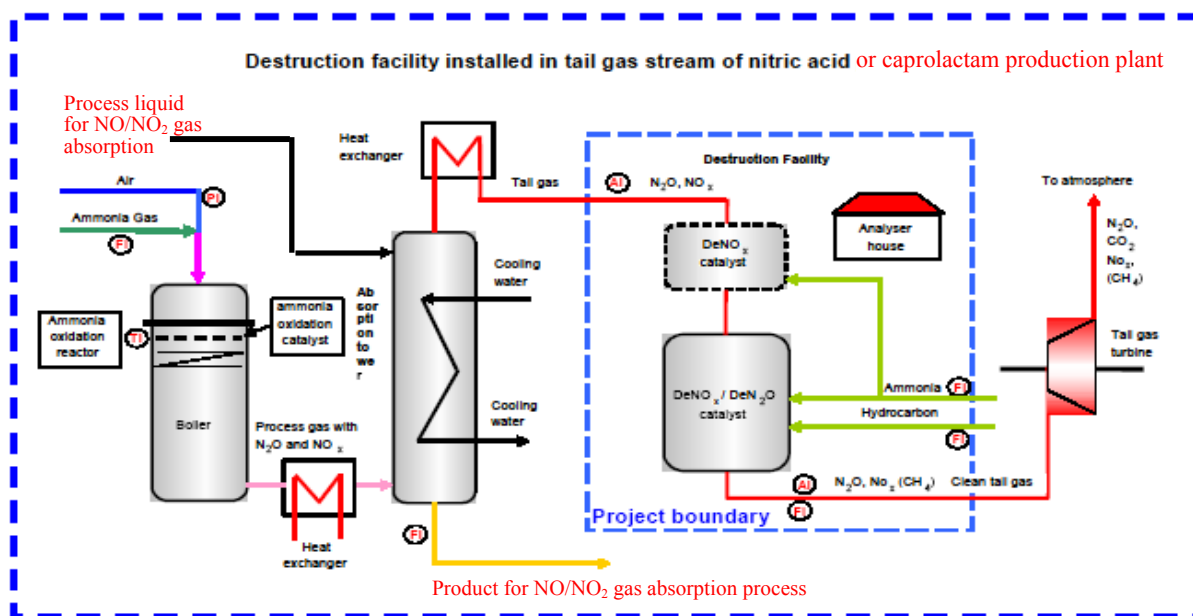

**Project Emissions**

<b>Source</b>	<b>Gas</b>		<b>Justification/Explanation</b>
Emissions of N <sub>2</sub> O as a result of side reaction to the nitric acid or caprolactam production process	N <sub>2</sub> O	Included	Main emission source, taking national N <sub>2</sub> O emission regulations into account.
Emissions related to the production of ammonia used for NO <sub>x</sub> reduction (Attention: Ammonia used for NO <sub>x</sub> reduction does not cause GHG emissions, only the production of ammonia causes GHG emissions)	CO <sub>2</sub> CH <sub>4</sub> N <sub>2</sub> O	Included	In case SCR De NO <sub>x</sub> unit is already installed prior to the project start: ammonia input for SCR is considered to be of the same magnitude to project related ammonia input for NO <sub>x</sub> reduction. Baseline emissions and project emissions are similar and therefore not considered for calculation. In case no SCR De NO <sub>x</sub> -unit is already installed prior to the project start: ammonia input for NO <sub>x</sub> reduction is considered 0 for baseline emissions.
In case of N <sub>2</sub> O reduction process installed: Emissions at the project site resulting from hydrocarbons used as reducing agent and/or re-heating the tail gas	CH <sub>4</sub> and/or CO <sub>2</sub>	Included	Hydrocarbons are used as reducing agent and/or re-heating the tail gas to enhance the efficiency of a N <sub>2</sub> O catalytic reduction facility. In this case hydrocarbons are mainly converted to CO <sub>2</sub> , while some hydrocarbons may remain intact. Fractions of unconverted methane are either measured (monitored online) or all methane used as reducing agent is assumed as completely unconverted. All other hydrocarbons, with more than 2 molecules of carbon, are assumed to be completely converted to CO <sub>2</sub> .
Emissions from electricity demand	CO <sub>2</sub> CH <sub>4</sub> N <sub>2</sub> O	Excluded	GHG emissions related to the electricity consumption are insignificant (< 0.005%) and are excluded as monitoring would lead to unreasonable costs.
Emissions related to the production of the hydrocarbons	CO <sub>2</sub> CH <sub>4</sub> N <sub>2</sub> O	Excluded	GHG emissions related to the production of hydrocarbons used as reducing agent represent less than 0.001% of expected emission reductions and will not be taken into account due to unreasonable costs for monitoring.

As shown in Figure 1, the spatial extent of the project boundary comprises:

- The catalytic  $N_2O$  destruction facility including auxiliary ammonia and/or hydrocarbon input; and
- For monitoring purposes only, the nitric acid or caprolactam production plant, to measure the nitric acid or caprolactam output and operating parameters of the ammonia oxidation reactor.

**Figure 1: Project boundary**

### Identification of the baseline scenario

The determination of the baseline scenario consists of Steps 1 to 5 below. In the event of re-assessment of the baseline scenario in the course of proposed project activity (due to new or modified  $NO_x$  or  $N_2O$  emission regulations), re-assessment should be executed as specified in Step 6.

#### **Step 1: Identify technically feasible baseline scenario alternatives to the project activity**

The baseline scenario alternatives should include all technically feasible options which are realistic and credible.

**Step 1a: The baseline scenario alternatives should include all possible options that are technically feasible to handle  $N_2O$  emissions. These options are, inter alia:**

- Status quo: The continuation of the current situation, where there will be no installation of technology for the destruction or abatement of  $N_2O$ ;
- Switch to alternative production method not involving ammonia oxidation process;
- Alternative use of  $N_2O$  such as:
  - Recycling of  $N_2O$  as a feedstock for the plant;
  - The use of  $N_2O$  for external purposes.

- Installation of a Non-Selective Catalytic Reduction (NSCR) DeNO<sub>x</sub> unit;<sup>2</sup>
- The installation of an N<sub>2</sub>O destruction or abatement technology:
  - Tertiary measure for N<sub>2</sub>O destruction;
  - Primary or secondary measures for N<sub>2</sub>O destruction or abatement.

These options should include the CDM project activity not implemented as a CDM project.

***Step 1b: In addition to the baseline scenario alternatives of Step 1a, all possible options that are technically feasible to handle NO<sub>x</sub> emissions should be considered. The installation of a NSCR DeNO<sub>x</sub> unit could also cause N<sub>2</sub>O emission reduction. Therefore NO<sub>x</sub> emission regulations have to be taken into account in determining the baseline scenario. The respective options are, inter alia:***

- The continuation of the current situation, where either a DeNO<sub>x</sub>-unit is installed or not;
- Installation of a new Selective Catalytic Reduction (SCR) DeNO<sub>x</sub> unit;
- Installation of a new Non-Selective Catalytic Reduction (NSCR) DeNO<sub>x</sub> unit;
- Installation of a new tertiary measure that combines NO<sub>x</sub> and N<sub>2</sub>O emission reduction.

***Step 2: Eliminate baseline alternatives that do not comply with legal or regulatory requirements***

- (1) The baseline alternatives shall be in compliance with all applicable legal and regulatory requirements, even if these laws and regulations have objectives other than GHG reductions (N<sub>2</sub>O), e.g. national or local NO<sub>x</sub> regulations or byproduct waste. This Step does not consider national and local policies that do not have legally-binding status. Eliminate all baseline alternatives that do not comply with the legal and regulatory requirements on N<sub>2</sub>O and NO<sub>x</sub> emissions;
- (2) If an alternative does not comply with all applicable legislation and regulations, then show that, based on an examination of current practice in the country or region in which the law or regulation applies, those applicable legal or regulatory requirements are systematically not enforced and that non-compliance with those requirements is widespread in the country. If this cannot be shown, then eliminate the alternative from further consideration;
- (3) If the proposed project activity is the only alternative amongst the ones considered by the project participants that is in compliance with all regulations with which there is general compliance, then the proposed project activity is the baseline scenario.

---

<sup>2</sup> NSCR: As NSCR DeNO<sub>x</sub>-unit will reduce N<sub>2</sub>O emissions as a side reaction to the NO<sub>x</sub>-reduction. Consequently, new NSCR installation can be seen as alternative N<sub>2</sub>O reduction technology.

The following table shows potential baseline scenarios taking legal or regulatory requirements into account:

<i>Nitric Acid or Caprolactam Production Plant in compliance with N<sub>2</sub>O and NO<sub>x</sub> regulation</i>	<i>Nitric Acid or Caprolactam Production Plant not in compliance with NO<sub>x</sub> regulation</i>	<i>Nitric Acid or Caprolactam Production Plant not in compliance with N<sub>2</sub>O regulation</i>
Continuation Status quo	SCR DeNO <sub>x</sub> installation N	SCR De NO <sub>x</sub> installation that combines N <sub>2</sub> O and NO <sub>x</sub> emission reduction
Installation of N <sub>2</sub> O destruction or abatement technology	NSCR De NO <sub>x</sub> installation	Installation of N <sub>2</sub> O destruction or abatement technology
<i>Alternative use of N<sub>2</sub>O</i>	<i>Tertiary measure that combines NO<sub>x</sub> and N<sub>2</sub>O emission reduction</i>	<i>Alternative use of N<sub>2</sub>O</i>

**Step 3: Eliminate baseline alternatives that face prohibitive barriers (barrier analysis)**

**Sub-Step 3a: On the basis of the alternatives that are technically feasible and in compliance with all legal and regulatory requirements, the project participant should establish a complete list of barriers that would prevent alternatives to occur in the absence of CDM. Barriers should include, among others:**

- Investment barriers, *inter alia*:
  - o Debt funding is not available for this type of innovative project activity;
  - o No access to international capital markets due to real or perceived risks associated with domestic or foreign direct investment in the country where the project activity is to be implemented.
- Technological barriers, *inter alia*:
  - o Technical and operational risks of alternatives;
  - o Technical efficiency of alternatives (e.g. N<sub>2</sub>O destruction, abatement rate);
  - o Skilled and/or properly trained labour to operate and maintain the technology is not available and no education/training institution in the host country provides the needed skill, leading to equipment disrepair and malfunctioning;
  - o Lack of infrastructure for implementation of the technology.
- Barriers due to prevailing practice, *inter alia*:
  - o The project activity is the “first of its kind”: No project activity of this type is currently operational in the host country or region.

Provide transparent and documented evidence, and offer conservative interpretations of this documented evidence, as to how it demonstrates the existence and significance of the identified barriers. Anecdotal evidence can be included, but alone is not sufficient proof of barriers. The type of evidence to be provided may include:

- (a) Relevant legislation, regulatory information or industry norms;
- (b) Relevant (sectoral) studies or surveys (e.g. market surveys, technology studies, *etc*) undertaken by universities, research institutions, industry associations, companies, bilateral/multilateral institutions *etc*;
- (c) Relevant statistical data from national or international statistics;

- (d) Documentation of relevant market data (e.g. market prices, tariffs, rules);
- (e) Written documentation from the company or institution developing or implementing the CDM project activity or the CDM project developer, such as minutes from Board meetings, correspondence, feasibility studies, financial or budgetary information, etc;
- (f) Documents prepared by the project developer, contractors or project partners in the context of the proposed project activity or similar previous project implementations;
- (g) Written documentation of independent expert judgements from industry, educational institutions (e.g. universities, technical schools, training centres), industry associations and others.

***Sub-Step 3b: Show that the identified barriers would not prevent the implementation of at least one of the alternatives (except the proposed CDM project activity):***

If any of the baseline scenario alternatives face barriers that would prohibit them from being implemented, then these should be eliminated.

If all project alternatives are prevented by at least one barrier, either the proposed CDM project is itself the baseline or the set of project alternatives has to be completed to include the potential baseline.

If there are several potential baseline scenario candidates, either choose the most conservative alternative as a baseline scenario and go to Step 5, otherwise go to Step 4.

***Step 4: Identify the most economically attractive baseline scenario alternative***

Determine which of the remaining project alternatives that are not prevented by any barrier is the most economically or financially attractive.

To conduct the investment analysis, use the following Sub-steps:

***Sub-step 4a: Determine appropriate analysis method:***

Determine whether to apply a simple cost analysis or an investment comparison analysis. If all remaining project alternatives generate no financial or economic benefits other than CDM related income, then apply the simple cost analysis (Option I). Otherwise, use the investment comparison analysis (Option II).

***Sub-step 4b: Option I: Apply simple cost analysis:***

Document the costs associated with alternatives to the CDM project activity and demonstrate that the corresponding activities produce no financial or economic benefits.

- If all alternatives do not generate any financial or economic benefits, then the least costly alternative among these alternative is pre-selected as the most plausible baseline scenario candidate;
- If one or more alternatives generate financial or economic benefits, then the simple cost analysis cannot be used to select the baseline scenario.

***Sub-step 4c: Option II: Apply investment comparison analysis:***

Identify the financial indicator, such as IRR,<sup>3</sup> NPV, cost benefit ratio, or unit cost of service most suitable for the project type and decision-making context.

Calculate the suitable financial indicator for each of the project alternatives that have not been eliminated in Step 3 and include all relevant costs (including, for example, the investment cost, the operations and maintenance costs, financial costs, etc.) and revenues (including subsidies/fiscal incentives 3, etc. where applicable), and, as appropriate, non-market costs and benefits in the case of public investors.

Present the investment analysis in a transparent manner and provide all the relevant assumptions in the CDM-PDD, so that a reader can reproduce the analysis and obtain the same results. Clearly present critical techno-economic parameters and assumptions (such as capital costs, fuel prices, lifetimes, and discount rate or cost of capital). Justify and/or cite assumptions in a manner that can be validated by the DOE. In calculating the financial indicator, the project's risks can be included through the cash flow pattern, subject to project-specific expectations and assumptions (e.g. insurance premiums can be used in the calculation to reflect specific risk equivalents).

Assumptions and input data for the investment analysis shall not differ across the project activity and its alternatives, unless differences can be well substantiated.

Present in the CDM-PDD submitted for validation a clear comparison of the financial indicator for the proposed project alternative.

The alternative that has the best indicator (e.g. highest IRR) can be pre-selected as the most plausible baseline scenario candidate.

***Sub-step 4d: Sensitivity analysis (only applicable to Option II)***

Include a sensitivity analysis that shows whether the conclusion regarding the financial attractiveness is robust to reasonable variations in the critical assumptions. The investment analysis provides a valid argument in selecting the baseline only if it consistently supports (for a realistic range of assumptions) the conclusion that the pre-selected baseline scenario candidate is likely to remain the most financially and/or economically attractive.

In case the sensitivity analysis is not fully conclusive, select the most conservative among the project alternatives that are the most financially and/or economically attractive according to both Steps 4.c and the sensitivity analysis in the Step 4.d, e.g., if the sensitivity analysis shows that one or more project alternatives compete with the one identified in Step 4.c., select the alternative with the lowest GHG emissions.

***Step 5: Re-assessment of Baseline Scenario in course of proposed project activity's lifetime***

At the start of a crediting period, a re-assessment of the baseline scenario due to new or modified NO<sub>x</sub> or N<sub>2</sub>O emission regulations should be executed as follows:

---

<sup>3</sup> For the investment comparison analyses, IRRs can be calculated either as project IRRs or as equity IRRs. Project IRRs calculate a return based on project cash outflows and cash inflows only, irrespective of the source of financing. Equity IRRs calculate a return to equity investors and therefore also consider amount and costs of available debt financing. The decision to proceed with an investment is based on returns to the investors, so equity IRR will be more appropriate in many cases. However, there will also be cases where a project IRR may be appropriate.

**Sub Step 5a: New or modified NO<sub>x</sub>-emission regulations**

If new or modified NO<sub>x</sub> emission regulations are introduced after the project start, determination of the baseline scenario will be re-assessed at the start of a crediting period. Baseline scenario alternatives to be analysed should include, *inter alia*:

- Selective Catalytic Reduction (SCR);
- Non-Selective Catalytic Reduction (NSCR);
- Tertiary measures incorporating a selective catalyst for destroying N<sub>2</sub>O and NO<sub>x</sub> emissions;
- Continuation of baseline scenario.

For the determination of the adjusted baseline scenario the project participant should re-assess the baseline scenario and shall apply baseline determination process as stipulated above (Steps 1 – 5).

Potential outcomes of the re-assessment of the Baseline Scenario (to be in line with NO <sub>x</sub> regulation)	Consequence (adjusted baseline scenario)
SCR De NO <sub>x</sub> installation	Continuation of original (N <sub>2</sub> O) baseline scenario
NSCR De NO <sub>x</sub> installation	The N <sub>2</sub> O emissions outlet of NSCR become adjusted baseline N <sub>2</sub> O emissions, as NSCR may reduce N <sub>2</sub> O emissions as well as NO <sub>x</sub> .
Tertiary measure that combines NO <sub>x</sub> and N <sub>2</sub> O emission reduction	Adjusted baseline scenario results in zero N <sub>2</sub> O emissions reduction
Continuation of original baseline scenario	Continuation of original baseline scenario

**Sub Step 5b: New or modified N<sub>2</sub>O -regulation**

If legal regulations on N<sub>2</sub>O emissions are introduced or changed during the crediting period, the baseline emissions shall be adjusted at the time the legislation has to be legally implemented.

The methodology is applicable if the procedure to identify the baseline scenario results in that the most likely baseline scenario is the continuation of emitting N<sub>2</sub>O to the atmosphere, without the installation of N<sub>2</sub>O destruction or abatement technologies, including technologies that indirectly reduce N<sub>2</sub>O emissions (e.g. NSCR DeNO<sub>x</sub> units).

**Additionality**

The additionality of the project activity shall be demonstrated and assessed using the latest version of the “Tool for demonstration and assessment of additionality” agreed by the Executive Board.

Because of the similarity of both approaches used to determine the baseline scenario and the additionality tool, Step 1 of the “Tool for demonstration and assessment of additionality” can be ignored.

Consistency shall be ensured between the baseline scenario determination and additionality demonstration. The baseline scenario alternative selected in the previous section shall be used when applying Steps 2 to 5 of the “Tool for demonstration and assessment of additionality” In case of re-assessment of baseline scenario (as a consequence of new NO<sub>x</sub> regulations) in course of proposed project activity’s lifetime, the re-assessment has to be undertaken according to section 4. Furthermore, the additionality test shall be undertaken again.

## Project Emissions

The emissions due to the project activity are composed of (a) the emissions of not destroyed N<sub>2</sub>O and (b) emissions from auxiliary ammonia and hydrocarbons input resulting from the operation of the N<sub>2</sub>O destruction facility. The procedure of determining the project N<sub>2</sub>O emissions is similar to that used for determining baseline emissions.

Project emissions are defined by the following equation:

$$PE_y = PEND_{y,y} + PEDF_{y,y} \quad (1)$$

Where:

- PE<sub>y</sub> = Project emissions in year y (tCO<sub>2</sub>e)
- PEND<sub>y,y</sub> = Project emissions from N<sub>2</sub>O not destroyed in year y (tCO<sub>2</sub>e)
- PEDF<sub>y,y</sub> = Project emissions related to the operation of the destruction facility in year y (tCO<sub>2</sub>e)

### 1.1. N<sub>2</sub>O emissions not destroyed by the project activity

N<sub>2</sub>O emissions not destroyed by the project activity are calculated based on the continuous measurement of the N<sub>2</sub>O concentration in the tail gas of the N<sub>2</sub>O destruction facility and the volume flow rate of the tail gas stream.

The emissions of non destroyed N<sub>2</sub>O are given by:

$$PEND_{y,y} = PEN_{2O,y} \times GWPN_{2O} \quad (2)$$

Where:

- PEND<sub>y,y</sub> = Project emissions from N<sub>2</sub>O not destroyed in year y (tCO<sub>2</sub>e)
- PEN<sub>2O,y</sub> = Project emissions of N<sub>2</sub>O in year y (tN<sub>2</sub>O)
- GWPN<sub>2O</sub> = Global warming potential of N<sub>2</sub>O = 310

$$PEN_{2O,y} = \sum_{i=1}^n F_{TE,i} \times CON_{2O,i} \times M_i \quad (3)$$

Where:

- PEN<sub>2O,y</sub> = Project emissions of N<sub>2</sub>O in year y (tN<sub>2</sub>O)
- FTE<sub>i</sub> = Volume flow rate at the exit of the destruction facility during interval i (m<sup>3</sup>/h)<sup>4</sup>
- CON<sub>2O,i</sub> = N<sub>2</sub>O concentration in the tail gas of the N<sub>2</sub>O destruction facility during interval i (tN<sub>2</sub>O/m<sup>3</sup>)
- M<sub>i</sub> = Length of measuring interval i (h)
- i = Interval
- n = Number of intervals during the year

<sup>4</sup> FTE<sub>i</sub> and CON<sub>2O,i</sub> should be measured simultaneously and at same basis (wet or dry) and values should be expressed on the same basis (wet or dry) and should be corrected to normal conditions (101.325 kPa, 0 deg C). If the instrument (or measurement system) uses an algorithm to convert actual conditions to normal conditions, the proper source of such an algorithm should be used (e.g. based on procedures of EN14181). For all the cases, either manual or algorithm-based conversion of actual conditions to normal conditions, the temperature and pressure of actual conditions of gas should be recorded.

## 1.2. Project emissions from the operation of the destruction facility

The operation of the N<sub>2</sub>O destruction facility may require the use of ammonia and hydrocarbon (e.g. natural gas, LPG, butane) as input streams.

The emissions related to the operation of the N<sub>2</sub>O destruction facility are given by (1) upstream emissions related to the production of ammonia used as input and (2) on-site emissions due to the hydrocarbons use as input to the N<sub>2</sub>O destruction facility:

$$PEDF_{,y} = PENH3_{,y} + PEHC_{,y} \quad (4)$$

Where:

- $PEDF_{,y}$  = Project emissions related to the operation of the destruction facility in year y (tCO<sub>2</sub>e)  
 $PENH3_{,y}$  = Project emissions related to ammonia input to destruction facility in year y (tCO<sub>2</sub>e)  
 $PEHC_{,y}$  = Project emissions related to hydrocarbon input to destruction facility and/or re-heater in year y (tCO<sub>2</sub>e)

### Ammonia Input to the destruction facility:

- In case an existing SCR DeNO<sub>x</sub> unit is already installed prior to the starting date of the project activity or has to be installed according to legal requirements, the project ammonia input will be considered equal to the ammonia input of the baseline scenario;
- Should no SCR DeNO<sub>x</sub> unit be installed prior to the starting date of the project activity, project emissions related to the production of ammonia are considered as follows:

$$PENH3_{,y} = QNH3_{,y} \times EFNH3 \quad (5)$$

Where:

- $PENH3_{,y}$  = Project emissions related to ammonia input to destruction facility in year y (tCO<sub>2</sub>e)  
 $QNH3_{,y}$  = Ammonia input to the destruction facility in year y (tNH<sub>3</sub>)  
 $EFNH3$  = GHG emissions factor for ammonia production (CO<sub>2</sub>e/tNH<sub>3</sub>)

Please note: Ammonia input for NO<sub>x</sub> emission reduction will not cause GHG emissions other than related to the production of ammonia.

A default factor of 2.14 tCO<sub>2</sub>e/tNH<sub>3</sub> is suggested (GEMIS 4.2).

### Hydrocarbon Input:

Hydrocarbons can be used as reducing agent and/or re-heating the tail gas to enhance the catalytic N<sub>2</sub>O reduction efficiency. In this case hydrocarbons are mainly converted to CO<sub>2</sub> ( $HCEC_{,y}$ ), while some methane remain unconverted to CO<sub>2</sub> ( $HCENC_{,y}$ ).

The fraction of the converted hydrocarbons is OXIDHC.

$$PEHC_{,y} = HCEC_{,y} + HCENC_{,y} \quad (6)$$

Where:

- $PEHC_{,y}$  = Project emissions related to hydrocarbon input to destruction facility and/or re-heater in year y (tCO<sub>2</sub>e)  
 $HCEC_{,y}$  = Converted hydrocarbon emissions in year y (tCO<sub>2</sub>)  
 $HCENC_{,y}$  = Methane emissions in year y (tCO<sub>2</sub>e)

For calculation of the GHG emissions related to the hydrocarbons converted and not converted, the following formulae are used:

$$HCE_{NC,y} = \rho_{CH_4} \times Q_{CH_4,y} \times GWP_{CH_4} \times (1 - OXID_{CH_4}/100) \quad (7)$$

Where:

$HCE_{NC,y}$	=	Methane emissions in year y (tCO <sub>2</sub> e)
$\rho_{CH_4}$	=	Methane density (t/m <sup>3</sup> )
$Q_{CH_4,y}$	=	Methane used in year y (m <sup>3</sup> )
$GWP_{CH_4}$	=	Global warming potential of methane
$OXID_{CH_4}$	=	Oxidation factor of methane (%)

$$HCE_{C,y} = \rho_{HC} \times Q_{HC,y} \times EF_{HC} \times OXID_{HC}/100 + \rho_{CH_4} \times Q_{CH_4,y} \times OXID_{CH_4}/100 \quad (8)$$

Where:

$HCE_{C,y}$	=	Converted hydrocarbon emissions in year y (tCO <sub>2</sub> e)
$\rho_{HC}$	=	Hydrocarbon density (t/m <sup>3</sup> )
$Q_{HC,y}$	=	Hydrocarbon, with two or more molecules of carbon, input in year y (m <sup>3</sup> )
$OXID_{HC}$	=	Oxidation factor of hydrocarbon (%), with two or more molecules of carbon
$EF_{HC}$	=	Carbon emissions factor of hydrocarbon (tCO <sub>2</sub> /t HC), with two or more molecules of carbon

The hydrocarbon CO<sub>2</sub> emission factor is given by the molecular weights and the chemical reaction when hydrocarbons are converted (e.g. where CH<sub>4</sub> is used as hydrocarbon, each converted tonne of CH<sub>4</sub> results in 44/16 tonnes of CO<sub>2</sub>, thus the hydrocarbon emission factor is 2.75).

Project emissions are limited to the design capacity of the existing nitric acid or caprolactam production plant. If the actual production of nitric acid or caprolactam ( $P_{product,y}$ ) exceeds the design capacity ( $P_{product,max}$ ) then emissions related to the production above  $P_{product,max}$  will neither be claimed for the baseline nor for the project scenario.

### Baseline Emissions

Baseline emissions are given by the following equation:

$$BE_y = BEN_{2O} \times GWP_{N_2O} \quad (9)$$

Where:

$BE_y$	=	Baseline emissions in year y (tCO <sub>2</sub> e)
$BEN_{2O,y}$	=	Baseline emissions of N <sub>2</sub> O in year y (tN <sub>2</sub> O)
$GWP_{N_2O}$	=	Global warming potential of N <sub>2</sub> O = 310

Depending on the implementation of regulations on N<sub>2</sub>O emissions and the character of the regulation, baseline N<sub>2</sub>O emissions ( $BEN_{2O,y}$ ) are calculated as shown below:

**Case 1:** The most plausible baseline scenario is that no N<sub>2</sub>O would be abated in the absence of the project activity (i.e. no secondary or tertiary reductions measures and no NSCR DeNO<sub>x</sub> unit would be installed).

$$BEN_{2O,y} = Q_{N_2O,y} \quad (10)$$

Where:

$BEN_{2O,y}$  = Baseline emissions of  $N_2O$  in year  $y$  (t $N_2O$ )

$QIN_{2O,y}$  = Quantity of  $N_2O$  supplied to the destruction facility in year  $y$  (t $N_2O$ )

The quantity of  $N_2O$  supplied to the  $N_2O$  destruction facility (DF) is calculated based on continuous measurement of the tail gas volume flow rate and the  $N_2O$  concentration at the inlet of the  $N_2O$  destruction facility. Therefore the quantity of the  $N_2O$  at the inlet is given by:

$$QIN_{2O,y} = \sum_{i=1}^n F_{TL,i} \times CIN_{2O,i} \times M_i \quad (11)$$

Where:

$QIN_{2O,y}$  = Quantity of  $N_2O$  emissions at the inlet of the destruction facility in year  $y$  (t $N_2O$ )

$F_{TL,i}$  = Volume flow rate at the inlet of the destruction facility during interval  $i$  (m<sup>3</sup>/h)<sup>5</sup>

$CIN_{2O,i}$  =  $N_2O$  concentration a destruction facility inlet during interval  $i$  (t $N_2O$ /m<sup>3</sup>)

$M_i$  = Length of measuring interval  $i$  (h)

$i$  = Interval

$n$  = Number of intervals during the year

Baseline emissions are limited to the design capacity of the existing nitric acid or caprolactam production plant. If the actual production of nitric acid or caprolactam ( $P_{product,y}$ ) exceeds the design capacity ( $P_{product,max}$ ) then emissions related to the production above  $P_{product,max}$  will neither be claimed for the baseline nor for the project scenario.

If,  $P_{product,y} > P_{product,max}$  (12)

Then

$$BEN_{2O,y} = SEN_{2O,y} \times P_{product,max} \quad (13)$$

Where:

$BEN_{2O,y}$  = Baseline emissions of  $N_2O$  in year  $y$  (t $N_2O$ )

$SEN_{2O,y}$  = Specific  $N_2O$  emissions per unit of output product of nitric acid or caprolactam in year  $y$  (t $N_2O$ / t Product)

$P_{product,max}$  = Design capacity (t Product )

The specific  $N_2O$  emissions per unit of output of nitric acid or caprolactam is defined as:

$$SEN_{2O,y} = QIN_{2O,y} / P_{product,y} \quad (14)$$

Where:

$SEN_{2O,y}$  = Specific  $N_2O$  emissions per unit of output of nitric acid or caprolactam in year  $y$  (t $N_2O$ / t Product)

$QIN_{2O,y}$  = Quantity of  $N_2O$  emissions at the inlet of the destruction facility in year  $y$  (t $N_2O$ )

$P_{product,y}$  = Production of nitric acid or caprolactam in year  $y$  (t Product)

<sup>5</sup> FTE<sub>i</sub> and CIN<sub>2O,i</sub> should be measured simultaneously and at same basis (wet or dry) and values should be expressed on the same basis (wet or dry) and should be corrected to normal conditions (101.325 kPa, 0 deg C) . If the instrument (or measurement system) uses the algorithm to convert actual conditions to normal conditions, the proper source of such algorithm should be used (e.g. based on procedures of EN14181). For all the cases, either manual or algorithm-based conversion of actual conditions to normal conditions, the temperature and pressure of actual conditions of gas should be recorded.

**Case 2:** Legal regulations for N<sub>2</sub>O are implemented:

In case national regulations concerning N<sub>2</sub>O emissions are implemented during the crediting period, the impact on baseline N<sub>2</sub>O emissions is considered without any delay by adjusting the measured N<sub>2</sub>O emissions at the time the regulation has to be implemented. Depending on the character of the regulation the adjustment is done as shown below:

**Case 2.1:** Regulation setting of a threshold for an absolute quantity of N<sub>2</sub>O emissions per nitric acid or caprolactam production plant over a given time period:

Baseline N<sub>2</sub>O emissions are limited by the absolute quantity of N<sub>2</sub>O emissions given by the regulation. If the measured baseline N<sub>2</sub>O emissions are exceeding the regulatory limit, then measured baseline N<sub>2</sub>O emissions are substituted by the regulatory limit.

This leads to the following condition:

If,

$$QIN_{2O,y} > QRN_{2O,y} \quad (15)$$

then,

$$BEN_{2O,y} = QRN_{2O,y} \quad (16)$$

else,

$$BEN_{2O,y} = \min \text{ of } [QIN_{2O,y}, SEN_{2O,y} \times P_{\text{product,max}}] \quad (17)$$

Where:

$QIN_{2O,y}$  = Quantity of N<sub>2</sub>O emissions at the inlet of the destruction facility in year y (tN<sub>2</sub>O)

$QRN_{2O,y}$  = Regulatory limit of N<sub>2</sub>O emissions in year y (tN<sub>2</sub>O)

$BEN_{2O,y}$  = Baseline emissions of N<sub>2</sub>O in year y (tN<sub>2</sub>O)

$SEN_{2O,y}$  = Specific N<sub>2</sub>O emissions per unit of output of nitric acid or caprolactam in year y (tN<sub>2</sub>O/t Product)

$P_{\text{product,y}}$  = Production of nitric acid or caprolactam in year y (t Product)

The quantity of N<sub>2</sub>O emissions at the inlet of the N<sub>2</sub>O destruction facility (DF) is calculated based on continuous measurement of the tail gas volume flow rate and the N<sub>2</sub>O concentration at the inlet of the N<sub>2</sub>O destruction facility (see equation 11).

**Case 2.2:** Regulation setting of a threshold for specific N<sub>2</sub>O emissions per unit of product:

This leads to the following condition: If,

$$SEN_{2O,y} > RSEN_{2O} \quad (18)$$

then,

$$BEN_{2O,y} = \min \text{ of } [RSEN_{2O} \times P_{\text{product,y}}, SEN_{2O,y} \times P_{\text{product,max}}] \quad (19)$$

else,

$$BEN_{2O,y} = \min \text{ of } [QIN_{2O,y}, SEN_{2O,y} \times P_{\text{product,max}}] \quad (20)$$

Where:

$SEN_{2O,y}$	=	Specific $N_2O$ emissions per unit of output of nitric acid or caprolactam in year y (t $N_2O$ /t Product)
$RSEN_{2O}$	=	Regulatory limit of $N_2O$ emissions per unit of output of nitric acid or caprolactam (t $N_2O$ / t Product)
$BEN_{2O,y}$	=	Baseline emissions of $N_2O$ in year y (t $N_2O$ )
$P_{product,y}$	=	Production of nitric acid or caprolactam in year y (t Product)
$QIN_{2O,y}$	=	Quantity of $N_2O$ emissions at the inlet of the destruction facility in year y (t $N_2O$ )

The specific  $N_2O$  emissions per unit of output of nitric acid or caprolactam is defined as:

$$SEN_{2O,y} = QIN_{2O,y} / P_{product,y} \quad (21)$$

Where:

$SEN_{2O,y}$	=	Specific $N_2O$ emissions per unit of output of nitric acid or caprolactam in year y (t $N_2O$ / t Product)
$QIN_{2O,y}$	=	Quantity of $N_2O$ emissions at the inlet of the destruction facility in year y (t $N_2O$ )
$P_{product,y}$	=	Production of nitric acid or caprolactam in year y (t Product)

The quantity of  $N_2O$  emissions at the inlet of the  $N_2O$  destruction facility is calculated based on continuous measurement of the tail gas volume flow rate and the  $N_2O$  concentration at the inlet of the  $N_2O$  destruction facility (see equation 11).

**Case 2.3:** Regulation setting of a threshold for  $N_2O$  concentration in the tail gas

This leads to the following condition:

If,

$$CN_{2O,i} > CRN_{2O} \quad (22)$$

Then

$$BEN_{2O,y} = \sum_i^n CN_{2O,i} \times [F_{TG,i} \times M_i] \quad (23)$$

Where  $CN_{2O,i}$  is  $\min [CN_{2O,y}, CRN_{2O}, \text{and } \{(SEN_{2O,y} \times P_{product,max}) / (\sum(FTE_{E,i} * M_i))\}]$

else,

$$BEN_{2O,y} = QIN_{2O,y} \quad (24)$$

Where:

$CN_{2O,i}$	=	$N_2O$ concentration a destruction facility inlet during interval i (t $N_2O$ /m <sup>3</sup> )
$CRN_{2O,i}$	=	Regulatory limit for specific $N_2O$ concentration during interval i (t $N_2O$ /m <sup>3</sup> )
$BEN_{2O,y}$	=	Baseline emissions of $N_2O$ in year y (t $N_2O$ )
$FTE_{E,i}$	=	Volume flow rate at the exit of the destruction facility during interval i (m <sup>3</sup> /h)
$M_i$	=	Length of measuring interval i (h)
$i$	=	Interval
$n$	=	Number of intervals during the year
$QIN_{2O,y}$	=	Quantity of $N_2O$ emissions at the inlet of the destruction facility in year y (t $N_2O$ )

The quantity of  $N_2O$  emissions at the inlet of the  $N_2O$  destruction facility is calculated based on continuous measurement of the tail gas volume flow rate and the  $N_2O$  concentration at the inlet of the  $N_2O$  destruction facility (see equation 11).

Change in NO<sub>x</sub> or N<sub>2</sub>O regulations will automatically cause a re-assessment of the baseline scenario.

**Procedures used to determine the permitted operating conditions of the nitric acid or caprolactam production plant in order to avoid “overestimation of emission reductions”**

In order to avoid that the operation of the nitric acid or caprolactam production plant is manipulated in a way to increase the N<sub>2</sub>O generation, thereby increasing the CERs, the following procedures relating to the operating temperature and pressure and the use of ammonia oxidation catalysts shall be applied.

1. Operating temperature and pressure of the ammonia oxidation reactor (AOR):

If the actual average daily operating temperature or pressure in the ammonia oxidation reactor ( $T_g$  and  $P_g$ ) are outside a “permitted range” of operating temperatures and pressures ( $T_{g,hist}$  and  $P_{g,hist}$ ), the baseline emissions are calculated for the respective time period based on lower value between (a) the conservative IPCC default values of the latest IPCC GHG Inventory Guidelines accepted by the IPCC<sup>6</sup> for the equivalent N<sub>2</sub>O emission process. For nitric acid plants, the figure shall be 4.5kgN<sub>2</sub>O/tonne of nitric acid, whereas for caprolactam the figure shall be 5.4kgN<sub>2</sub>O/tonne of caprolactam, both conservatively applying the IPCC default values, (b)  $SEN_{2O,y}$  and (c) any related value as a result of legal regulations (e.g.  $RSEN_{2O,y}$ ).

Required monitoring parameters:

$T_{g,d}$	Actual operating temperature AOR on day $d$ (°C)
$P_{g,d}$	Actual operating pressure AOR on day $d$ (Pa)
$T_{g,hist}$	Historical operating temperature range AOR (°C)
$P_{g,hist}$	Historical operating pressure range AOR (Pa)

In order to determine the “permitted range” of the operating temperature and pressure in the ammonia oxidation reactor, the project applicant has the obligation to determine the operating temperature and pressure range by:

- Firstly, data on historical temperature and pressure ranges; or, if no data on historical temperatures and pressures are available; then
- Secondly, by range of temperature and pressure stipulated in the operating manual for the existing equipment; or, if no operating manual is available or the operating manual gives insufficient information; then
- Thirdly, by literature reference (e.g. from Ullmann’s Encyclopedia of Industrial Chemistry, Fifth, completely revised edition, Volume A 17, VCH, 1991, P. 298, Table 3. or other standard reference work or literature source).

If historical data on daily operating temperatures and pressures are available (*i.e.* case a), statistical analysis shall be used for determining the permitted range of operating temperature and pressure. To exclude the possibility of manipulating the process, outliers of historical operating temperature and pressure shall be eliminated by statistical methods. Therefore, the time series data are interpreted as a sample from a stochastic variable. All data that are part of the 2.5% Quantile or that are part of the (100-2.5)% Quantile of the sample distribution are defined as outliers and shall be eliminated. The permitted range of operating temperature and pressure is then calculated based on the remaining historical minimum and maximum operating conditions.

<sup>6</sup> According to Pre-publication Draft 2006 IPCC Guidelines accepted by the 21<sup>st</sup> Session of the IPCC, the conservative IPCC default value of Nitric Acid Plants is based on the default emission factor for low-pressure plants (5kgN<sub>2</sub>O/tonne of nitric acid, accounting for 10% uncertainty factor), whereas for caprolactam plants using Raschig process are 9 kgN<sub>2</sub>O/tonne of nitric acid, accounting for 40% uncertainty factor.

If a permissible operating limit is exceeded, the baseline N<sub>2</sub>O emissions for that period are capped at 4.5kgN<sub>2</sub>O/tonne of nitric acid, whereas for caprolactam the figure shall be 5.4kgN<sub>2</sub>O/tonne of caprolactam, both conservatively applying the IPCC default values.

## 2. Composition of ammonia oxidation catalyst:

The plant operator is allowed to use compositions of ammonia oxidation catalysts that are common practice in the region or have been used in the nitric acid or caprolactam production plant during the last three years without limitation of N<sub>2</sub>O baseline emissions.

In case the nitric acid or caprolactam production plant operator wishes to change to a composition not used during the last three years, but is common practice in the region and supplied by a reputable manufacturer, or if it corresponds to a composition that is reported as being in use in the relevant literature, the plant operator is allowed to use these ammonia oxidation catalysts without limitation of N<sub>2</sub>O baseline emissions.

In case the nitric acid or caprolactam production plant operator changes the composition of ammonia oxidation catalysts and the composition is not common practice in the region and not reported as being in use in the relevant literature, the project applicant has to demonstrate (either by economic or other arguments) that the choice of the new composition was based on considerations other than an attempt to increase the rate of N<sub>2</sub>O production. If the project applicant can demonstrate appropriate and verifiable reasons, the plant operator is allowed to use new ammonia oxidation catalysts without limitation of N<sub>2</sub>O baseline emissions.

The first composition of ammonia oxidation catalyst used during the crediting period shall be of the same kind of catalyst composition already in operation in the specific nitric acid or caprolactam production plant. This is to avoid gaming at the beginning of the project activity.

In case the nitric acid or caprolactam production plant operator changes the composition of ammonia oxidation catalysts and the composition is not common practice in the region and not reported as being in use in the relevant literature, and the project applicant **cannot** demonstrate appropriate and verifiable reasons for this.

Baseline emissions are limited to the maximum specific N<sub>2</sub>O emissions of previous periods (tN<sub>2</sub>O/tHNO<sub>3</sub> or tN<sub>2</sub>O/tCaprolactam), documented in the verified monitoring reports.

Required monitoring parameters:

<i>G</i> <sub>sup</sub>	Supplier of the ammonia oxidation catalyst
<i>G</i> <sub>sup,hist</sub>	Historical supplier of the ammonia oxidation catalyst
<i>G</i> <sub>com</sub>	Composition of the ammonia oxidation catalyst
<i>G</i> <sub>com,hist</sub>	Historical composition of the ammonia oxidation catalyst
<i>SEN</i> <sub>2O,y</sub>	Specific N <sub>2</sub> O emissions per ton of product of nitric acid or caprolactam in year y (tN <sub>2</sub> O/t Product)

## 3. Ammonia flow rate to the ammonia oxidation reactor:

If the actual daily ammonia flow rate exceeds the (upper) limit on maximum historical daily permitted ammonia flow rate, the baseline emissions for this operating day are calculated based on the conservative IPCC default values and are limited by the legal regulations. The upper limit on ammonia flow should be determined based on:

- Historical operating data on maximum daily average ammonia flow; or, if not existing; on
- Calculation of the maximum ammonia flow rate allowed as specified by ammonia oxidation catalyst manufacturer or on typical catalyst loadings; or, if not existing;
- Based on the literature.

If the daily ammonia input to the oxidation reactor exceeds the limit on permissible ammonia input, baseline N<sub>2</sub>O emissions are capped at conservative IPCC default values.

Required monitoring parameters on daily basis:

AOR <sub>d</sub>	Actual ammonia input to oxidation reactor (tNH <sub>3</sub> /day)
AOR <sub>hist</sub>	Maximum historical ammonia input to oxidation reactor (tNH <sub>3</sub> /day)

### Leakage

Each N<sub>2</sub>O destruction technology works best over a particular range of tail gas temperatures. Depending on the mode of operation, additional tail gas heating could be required upstream of the destruction facility. Appropriate tail gas temperature at the inlet of the N<sub>2</sub>O destruction facility could either be obtained due to external energy sources (e.g. additional heat exchanger) or by adjustments of the internal energy flow. In other words, the increased tail gas temperature at the inlet of the N<sub>2</sub>O destruction facility may require additional external energy, but the additional energy might be recovered before the tail gas is released to the atmosphere (e.g. tail gas turbine to generate electricity, kinetic energy or other).

On condition that an energy converter (e.g. tail gas turbine) is installed at the end of the pipe, the installation of the N<sub>2</sub>O destruction facility will not result in significant additional energy consumption at the nitric acid or caprolactam production plant and therefore no leakage is expected.

Leakage emissions need only be analyzed if the project activity does not involve any energy recovery from the tail gas. If an installation for energy utilization at the end of the pipe is missing, leakage is given by:

$$LE_y = LES_{y,y} + LETGU_{y,y} + LETGH_{y,y} \quad (25)$$

Where:

LE <sub>y</sub>	=	Leakage emissions in year y (tCO <sub>2</sub> e)
LES <sub>y,y</sub>	=	Emissions from net change steam export (tCO <sub>2</sub> e)
LETGU <sub>y,y</sub>	=	Emissions from net change in tail gas utilization (tCO <sub>2</sub> e)
LETGH <sub>y,y</sub>	=	Emissions from net change in tail gas heating (tCO <sub>2</sub> e)

Each component is calculated as follows:

$$LES_{y,y} = (STBL - STPR) \times My / \eta_{ST} \times EF_{ST} \quad (26)$$

Where:

LES <sub>y,y</sub>	=	Emissions from net change steam export (tCO <sub>2</sub> e)
STBL	=	Baseline steam export (MW)
STPR	=	Project steam export (MW)
My	=	Operating hours in year y (h)
η <sub>ST</sub>	=	Efficiency of steam generation (%)
EF <sub>ST</sub>	=	Fuel emissions factor for steam generation (tCO <sub>2</sub> e/MWh)

$$LETGU_{y,y} = (EEBL - EEPR) \times My / \eta_r \times EF_r \quad (27)$$

Where:

LETGU <sub>y</sub>	=	Emissions from net change in tail gas utilization (tCO <sub>2</sub> e)
EEBL	=	Baseline energy export from tail gas utilization (MW)
EEPJ	=	Project energy export from tail gas utilization (MW)
My	=	Operating hours in year y (h)
η <sub>r</sub>	=	Efficiency of replaced technology (%)
E <sub>Fr</sub>	=	Fuel emissions factor for replaced technology (tCO <sub>2</sub> e/MWh)

$$LETGH_{y,y} = (EITGH_{y,y} / \eta_{TGH}) \times EFTGH \quad (28)$$

Where:

LETGH <sub>y</sub>	=	Emissions from net change in tail gas heating (tCO <sub>2</sub> e)
EIBL <sub>y</sub>	=	Energy input for additional tail gas heating (MWh/yr)
η <sub>TGH</sub>	=	Efficiency of additional tail gas heating (%)
EFTGH	=	Emissions factor for additional tail gas heating (tCO <sub>2</sub> e/MWh)

The effect of the modifications on the energy balance (e.g. steam export) of the nitric acid or caprolactam production plant can be assessed by carrying out standard thermodynamic and heat transfer calculations. Since the overall effect is considered small, and the modifications adopted are highly project-specific, the calculation of the effects will be considered on a case-by-case basis at the project stage.

### Emission Reductions

The emission reduction  $ER_y$  by the project activity during a given year  $y$  is the difference between the baseline emissions ( $BE_y$ ) and project emissions ( $PE_y$ ), as follows:

$$ER_y = BE_y - PE_y - LE_y \quad (29)$$

Where:

ER <sub>y</sub>	=	Emissions reductions of the project activity during the year y (tCO <sub>2</sub> e)
BE <sub>y</sub>	=	Baseline emissions during the year y (tCO <sub>2</sub> e)
PE <sub>y</sub>	=	Project emissions during the year y (tCO <sub>2</sub> e)
LE <sub>y</sub>	=	Leakage emissions in year y (tCO <sub>2</sub> e)

## Approved monitoring methodology AM0028

### “Catalytic N<sub>2</sub>O destruction in the tail gas of Nitric Acid or Caprolactam Production Plants”

#### Sources

This monitoring methodology is based on NM0111 “Baseline Methodology for catalytic N<sub>2</sub>O destruction in the tail gas of Nitric Acid Plants” submitted by Carbon Projektentwicklung GmbH.

For more information regarding the proposals and their consideration by the Executive Board please refer to <http://cdm.unfccc.int/methodologies/PAmethodologies/approved.html>.

#### Applicability

The proposed methodology is applicable to project activities that destroy N<sub>2</sub>O emissions either by catalytic decomposition or catalytic reduction of N<sub>2</sub>O in the tail gas of nitric acid or caprolactam production<sup>7</sup> plants (*i.e.* tertiary destruction), where the following conditions apply:

- The applicability is limited to the existing production capacity measured in tonnes of nitric acid or caprolactam, where the commercial production had began no later than 31 December 2005. Definition of “existing” production capacity is applied for the process with the existing ammonia oxidization reactor where N<sub>2</sub>O is generated and not for the process with new ammonia oxidizer. Existing production “capacity” is defined as the designed capacity, measured in tons of nitric acid or caprolactam per year.
- Existing caprolactam plants are limited to those employing the Raschig process not using any external sources of nitrogen compounds other than feed ammonia.
- The project activity will not result in shut down of an existing N<sub>2</sub>O destruction or abatement facility at the nitric acid or caprolactam production plant;
- The project activity shall not affect the nitric acid or caprolactam production level;
- The project activity will not cause an increase in NO<sub>x</sub> emissions;
- In case a DeNO<sub>x</sub> unit is already installed prior to the start of the project activity, the installed DeNO<sub>x</sub> is a Selective Catalytic Reduction (SCR) DeNO<sub>x</sub> unit;
- The N<sub>2</sub>O concentration in the flow at the inlet and the outlet of the catalytic N<sub>2</sub>O destruction facility is measurable.

This monitoring methodology shall be used in conjunction with the approved baseline methodology AM0028 (Catalytic N<sub>2</sub>O destruction in the tail gas of Nitric Acid or Caprolactam Production Plants).

#### Methodology

The accuracy of the N<sub>2</sub>O emissions monitoring results is to be ensured by installing a monitoring system that has been certified to meet (or exceeds) the requirements of the prevailing best industry practice or monitoring standards in terms of operation, maintenance and calibration. The latest applicable European standards and norms (EN 14181) could be used as the basis for selecting and operating the monitoring system.

The value adopted for Quantity of N<sub>2</sub>O at the inlet of the destruction facility should be calculated considering conservatively the error included in the measurement.

---

<sup>7</sup> Caprolactam Production Plants including the ammonia oxidation reactor (AOR) where N<sub>2</sub>O is generated

**Determination of conversion rates of hydrocarbons:**

Hydrocarbons can be used as reducing agent and/or re-heating the tail gas. In the case of hydrocarbons with one carbon atom in the molecule (CH<sub>4</sub>), the hydrocarbon is mainly converted to CO<sub>2</sub>, while some remains intact. Hydrocarbon reducing agents with two or more carbon atoms in the molecule are completely converted to water, carbon monoxide and carbon dioxide (H<sub>2</sub>O, CO, CO<sub>2</sub>).

If methane (CH<sub>4</sub>) is present in the reducing agent and/or re-heating the tail gas, as with natural gas, a part leaves the N<sub>2</sub>O destruction facility unconverted and is emitted to atmosphere. The fraction of unconverted methane depends on the amount of methane supplied to the reactor, the reactor operating temperature, and the quantity of catalyst supplied.

**Case 1: Fraction of Methane not converted will be measured:**

In order to measure the fraction of unconverted methane, an additional analyser is required. If the project-specific costs of this analyser for CH<sub>4</sub> are not unreasonable the methodology recommends the installation of the analyser.

**Case 2: Fraction of Methane not converted will not be measured due to unreasonable costs**

A conservative baseline approach is required, as follows:

- If hydrocarbons with two or more carbon atoms are present as reducing agent:  
In order to apply a conservative baseline approach the fraction of unconverted hydrocarbons is zero: (OXIDHC = 100%). Hence, reducing agent GHG emissions are calculated based on the hydrocarbon CO<sub>2</sub> emission factor
- If methane is present in the reducing agent and/or re-heating the tail gas, for example; as with natural gas:  
In order to apply a conservative baseline approach the fraction of unconverted hydrocarbon is 100% (OXIDCH<sub>4</sub> = 0%). Hence, reducing agent GHG emissions are calculated based on the Global Warming Factor of the hydrocarbon.

The option to be adopted shall be decided on a case-by-case basis.

**Baseline emissions**

ID No.	Uncertainty level of data (High/Medium/Low)	QA/QC procedures planned for these data, or why such procedures are not necessary.
B1	Low	Cross – check of production, marketing and stock change data. Measurement devices such as weighbridge can be subjected to QA / QC scheme consistent with the procedures listed below, with respect to equipment certification, installation and performance.
B11; B12	Low	Pressure gauges subjected to QA / QC scheme consistent with the procedures listed below, with respect to equipment certification, installation and performance.
B4, P5	Low	Refer to QA / QC procedures cited below. FTI Both parameters shall be cross-checked to ensure that no leak of N <sub>2</sub> O is taking place. In case of discrepancy, conservative calculation of emission reduction shall be provided.
P6; B3	Low	Gas chromatography shall be subjected to relevant QA / QC scheme consistent with the procedures listed below, with respect to equipment certification, installation and performance.
P7	Low	No specific QA / QC procedures required
P10; P14; B18 L1	Low	Temperature meters subjected to QA / QC scheme consistent with the procedures listed below, with respect to equipment certification, installation and performance.

**Good monitoring practice and performance characteristics**

Accuracy of the N<sub>2</sub>O emissions monitoring results is to be ensured by installing a monitoring system that has been certified to meet or exceed the requirements of the prevailing best industry practice or monitoring standards in terms of operation, maintenance and calibration. The latest applicable European standards and norms (EN 14181) or equivalent standards, which prescribes the features needed for Automated Measuring Systems (AMS) need and how they are to be calibrated and maintained, shall be used as the basis for selecting and operating the monitoring system.

The following guidance documents are recommended as references for the Quality Assurance and Control procedures:

- (a) European Standard, Technical Committee Air Quality: Working Document, Air quality – Certification of automated measuring systems (AMS). Part 3: Performance specifications and test procedures for AMS for monitoring emissions from stationery sources, prEN 264022, CEN/TC 264:2005/1;
- (b) European Norm EN 14181: Quality assurance of automated measuring systems, 2004;
- (c) Bundesministerium für Umwelt, Naturschutz und Reaktorsicherheit (BMU), German Federal Ministry for the Environment, Nature Conservation and Nuclear Safety: Bundeseinheitliche Praxis bei der Überwachung der Emissionen. RdSchr. d. BMU v. 13.06.2005 – IG 12 – 45053/5.

The European Norm EN 14181 stipulates three levels of quality assurance tests and one annual functional test for AMS which are recommended to be used as guidance regarding the selection, installation and operation of the AMS under the monitoring methodology. The three quality assurance levels (QALs) are as follows:

- (1) Quality assurance of tested AMS. AMS must have performance certificate (e.g. MCERTS), with calculation of uncertainty before installation according to approved methods such as ISO 14956 including:
  - (a) Standard deviation; b) Lack of fit (linearity); c) Repeatability at zero and reference points; d) Time-dependent zero and span drift; e) Temperature dependence; f) Voltage fluctuation; g) Suitability test; h) Cross sensitivity to likely components of the stack gas; i) Influence of variations in flow rate on extractive Automated Measuring Systems; j) Response time; k) Detection limit; l) Influence of ambient conditions on zero and span readings; m) Performance and accuracy; n) Availability; o) Susceptibility to physical disturbances.

The specific performance characteristics of the monitoring system chosen by the project shall be listed in the Project Design Document. Also, project activities should calculate and show the margins of error for each of the performance characteristics as well as the cumulative error for the complete measuring system.

- (2) Quality assurance of installation and calibration of the Automated Measuring System according to the Standard Reference Measurement Method (SRM), determination of the measurement uncertainty/variability of the AMS and inspection of the compliance with the prescribed measurement uncertainties. Such tests must be carried out by organisations that have an accredited quality assurance system such as one according to ISO/IEC 17025 or relevant standards. Items to be considered include the following:
- (a) Selection of the location of measurement;
  - (b) Duly installation of the monitoring equipment;
  - (c) Correct choice of measurement range;
  - (d) Calibration of the AMS using the Standard-Reference-Method (SRM) as guidance;
  - (e) Calibration curve either as linear regression or as straight line from absolute zero to centre of a scatter-plot;
  - (f) Calculation of the standard deviation at the 95% confidence interval;
  - (g) Inspection every three years.
- (3) Continuous quality assurance through the local operator/manager (drift and accuracy of the AMS, verification management and documentation).
- (a) Permanent quality assurance during the plant operation by the operating staff;
  - (b) Assurance of reliable and correct operation of the monitoring equipment (maintenance evidence);
  - (c) Regular controls: zero point, span, drift, meet schedule of manufacturer maintenance intervals;

In addition, annual functionality test including SRM measurements to check for uncertainties in the data measured by the AMS. Such tests must be carried out by organisations that have an accredited quality assurance system such as one according to ISO/IEC 17025 or relevant standards.

- (a) Annual confirmation of the calibration curve;
- (b) Validity proof of calibration curves;
- (c) Back-setting of excess meter of invalid calibration range.

#### **Minimum requirements for electronic evaluation units**

- (a) Evaluation unit needs to take into account registration, mean average determination, validation, and evaluation;
- (b) The system and concept of emission data processing needs to be described;
- (c) Protocols and out-prints are required.

#### **Downtime of Automated Measuring System**

In the event that the monitoring system is down, the lowest between the conservative default value established in the methodology or the last measured byproduct rate (whichever the lower) will be valid and applied for the downtime period for the baseline emission factor, and the highest measured byproduct rate during the project activity will be applied for the downtime period for the campaign emission factor.

## History of the document

Version	Date	Nature of revision(s)
04.2	EB 41, Annex 8 02 August 2008	Editorial revision to add footnote 4 and footnote 5 to clarify that volume of gas and N <sub>2</sub> O concentration should be measured simultaneously, and at same basis (wet or dry) and should be expressed at the normal conditions. The clarification made in the monitoring tables of these parameters also.
04.1	25 January 2007	Equation 8 was modified by removing the term GWP on the lhs of the equation.
04	EB 28, Annex 11 21 December 2006	Conservative default value for oxidation of methane and hydrocarbons that may be used for destruction of NO <sub>x</sub> has been amended.
03	EB 27, Annex 8 01 November 2006	To clarify that the phrase “existing nitric acid production facilities installed no later than 31 December 2005” in the applicability conditions should be that a record of commercial production exists before 31 December, 2005.
02	EB 26, Annex 8 29 September 2006	To broaden the applicability of the approved methodology AM0028 to project activities that destroy N <sub>2</sub> O emissions from process of caprolactam production. The approved methodology was also amended to include the monitoring of N <sub>2</sub> O using the standard EN1418, which is also used in the approved methodology AM0034.
01	EB 23, Annex 13 24 February 2006	Initial adoption.
